Why to deal with turbulence in a CFD course?

- Most of the equations considered in **CFD are model** equations
- **Turbulence** is a phenomena which is present in $\approx 95\%$ of **CFD** applications
- **Turbulence** can only be very rarely simulated and usually **has to be modeled**
- **Basics** of turbulence are **required for the use** of the models

Our limitations, simplifications

description

Following effects are not considered:

- density variation ($\rho = \text{const.}$)
 - Shock wave and turbulence interaction excluded
 - Buoyancy effects on turbulence not treated
- viscosity variation ($\nu = \text{const.}$)
- effect of body forces ($g_i = 0$)
 - Except free surface flows, gravity has no effect, can be merged in the pressure

Precise definition?

- No definition exists for turbulence till now
- Stability, chaos theory are the candidate disciplines to provide a definition
 - But the describing PDE's are much more complicated to treat than an ODE
- Last unsolved problem of classical physics ('Is it possible to make a theoretical model to describe the statistics of a turbulent flow?')
- Engineers still can deal with turbulence

Reynolds number

- $Re = \frac{UL}{\nu} = \frac{F_{inertial}}{F_{viscous}}$
- high Re number \longleftrightarrow viscous forces are small
- **But** inviscid flow is not turbulent

Role of Re

- Reynolds number is the bifurcation (stability) parameter of the flow
- The $Re_{cr} \approx 2300$ for pipe flows

Statistical

description

- Vortex stretching (see e.g. Advanced Fluid Dynamics) is only present in 3D flows.
- In 2D there is no velocity component in the direction of the vorticity to stretch it.
- Responsible for **scale reduction**
- Responsible to **vorticity enhancement**

Averaged flow can be 2D

- Unsteady flowfield **must** be 3D
- The (Reynolds, time) averaged flowfield can be 2D
 - Spanwise fluctuations average to zero, but are required in the creation of streamwise, wall normal fluctuations

Statistical
description

Turbulent flow is unsteady, but unsteadiness does not mean turbulence

Stability of the unsteady flow can be different

- In a unsteady laminar pipe flow (e.g. $500 < Re_b(t) < 1000$), the dependency on small perturbations is smooth and continuous
- In a unsteady turbulent pipe flow (e.g. $5000 < Re_b(t) < 5500$), the dependency on small perturbations is strong

Continuum phenomena

- Can be described by the continuum Navier-Stokes (NS) equations
- I.e. no molecular phenomena is involve as it it was

Conclusions

- 1 Can be simulated by solving the NS equations (Direct Numerical Simulation = DNS)
- 2 A smallest scale of turbulence exist, which is usually remarkable bigger than the molecular scales
- 3 The are cases, where molecular effects are important (re-entry capsule)
- 4 Turbulence is not fed from molecular resonations, but is a property (stability type) of the solution of the NS

description

Diffusive property, the engineering consequence

- In the average turbulence usually increase transfers
 - E.g. friction factors are increased (e.g. λ)
 - Nusselt number is increased
- In the average turbulence usually increase transfer coefficients
 - Turbulent viscosity (momentum transfer) is increased
 - Turbulent heat conduction coefficient is increased
 - Turbulent diffusion coefficients are increased

description

Spatial spectrum

- Spatial spectrum is analogous to temporal one, defined by Fourier transformation
- Practically periodicity or infinite long domain is more difficult to find
- Visually: Flow features of every (between a bound) size are present

Counter-example

Acoustic waves have spike spectrum, with sub and super harmonics.

Has history, flow dependent, THE TURBULENCE does not exist

Statistical description

As formulated in the *last unsolved problem of classical physics* **no general rule** of the turbulence could be developed till now.

No universality of turbulence has been discovered

- Turbulent flows can be of different type, e.g.:
 - It can be boundary condition dependent
 - It depends on upstream condition (spatial history)
 - It depends on temporal history

The 'simple' approach

Turbulent flow can be characterised by its **time average** and the **fluctuation** compared to it

Problems of this approach

- How long should be the time average?
- How to distinguish between unsteadiness and turbulence?

description

Why to treat deterministic process by statistics?

- NS equations are deterministic (at least we believe, not proven generally)
- I.e. the solution is fully given by IC's and BC's
- Statistical description is useful because of the chaotic behaviour
 - The high sensitivity to the BC's and IC's
 - Possible to treat result of similar set of BC's and IC's statistically

Density variation visualise the different scales of turbulence in a mixing layer

Goal: Try to find some rules about the properties of turbulence at different scales

Kinetic energy

Kinetic energy:

$$E \stackrel{\text{def}}{=} \frac{1}{2} u_i u_i \quad (29)$$

Its Reynolds decomposition:

$$E = \frac{1}{2} u_i u_i = \frac{1}{2} (\bar{u}_i \bar{u}_i + 2u'_i \bar{u}_i + u'_i u'_i) \quad (30)$$

Its Reynolds average

$$\bar{E} = \underbrace{\frac{1}{2} (\bar{u}_i \bar{u}_i)}_{\hat{E}} + \underbrace{\frac{1}{2} (\overline{u'_i u'_i})}_k = \hat{E} + k \quad (31)$$

- The kinetic energy of the mean flow: \hat{E}
- The kinetic energy of the turbulence: k (Turbulent Kinetic Energy, TKE)

Conditions

Inlet Boundary
Conditions

High Re flow

- Typical velocity of the flow U
- Typical length scale of the flow \mathcal{L}
- Corresponding Reynolds number ($Re = \frac{U\mathcal{L}}{\nu}$) is high

Turbulence is made of vortices of different sizes

Each class of vortex has:

- length scale: l
- velocity scale: $u(l)$
- time scale: $\tau(l) = l/u(l)$

Richardson energy cascade

Boundary
Conditions

Inlet Boundary
Conditions

Biggest vortices

- size $l_0 \sim \mathcal{L}$
- velocity $u_0 = u_0(l_0) \sim u' = \sqrt{2/3k} \sim \mathcal{U}$

$\Rightarrow Re = \frac{u_0 l_0}{\nu}$ is also high

Fragmentation of the big vortices

- High Re corresponds to low viscous stabilisation
- Big vortices are unstable
- Big vortices break up into smaller ones

Richardson energy cascade

To the small scales

Boundary Conditions

Inlet Boundary Conditions

Dissipation equals production

- Dissipation is denoted by ε
- Because of the cascade can be characterised by large scale motion
- Dissipation: $\varepsilon \sim \frac{\text{kin. energy}}{\text{timescale}}$ @ the large scales
 - By formula: $\varepsilon = \frac{u_0^2}{l_0/u_0} = \frac{u_0^3}{l_0}$

NS symbol

For the description of development rules, it is useful to define the following NS symbol:

$$NS(u_i) \stackrel{\text{def}}{=} \partial_t u_i + u_j \partial_j u_i = \underbrace{-\frac{1}{\rho} \partial_i p + \nu \partial_j s_{ij}}_{\partial_j t_{ij}} \quad (32)$$

Let us repeat the development of the Reynolds equation!

$$\overline{NS(u_i)} \quad (33)$$

$$\partial_t \bar{u}_i + \bar{u}_j \partial_j \bar{u}_i = \partial_j \underbrace{\left[-\frac{1}{\rho} \bar{p} \delta_{ij} + \nu \bar{s}_{ij} - \overline{u'_i u'_j} \right]}_{\bar{T}_{ij}} \quad (34)$$

The TKE equation

Taking the trace of $\overline{(NS(u_i) - \overline{NS(u_i)})u'_j(NS(u_j) - \overline{NS(u_j)})u'_i}$

$$\partial_t k + \overline{u_j} \partial_j k = \underbrace{-a_{ij} \overline{s_{ij}}}_{\text{Production}} + \underbrace{\partial_j \left[\overline{u'_j \left(\frac{p'}{\rho} + k' \right) - \nu u'_i s'_{ij}} \right]}_{\text{Transport}} - \underbrace{\varepsilon}_{\text{Dissipation}} \quad (35)$$

- Dissipation: $\varepsilon \stackrel{\text{def}}{=} 2\nu \overline{s'_{ij} s'_{ij}}$
- Anisotropy tensor: $a_{ij} \stackrel{\text{def}}{=} \overline{u'_i u'_j} - \frac{1}{3} \underbrace{\overline{u'_l u'_l}}_{2k} \delta_{ij}$

Deviator part of the Reynolds stress tensor

Transport
equation of k

Modelling

Eddy Viscosity

Two equations
models

Boundary
Conditions

Inlet Boundary
Conditions

- Solving the Reynolds averaged NS for the averaged variables $(\bar{u}, \bar{v}, \bar{w}, \bar{p})$
- The Reynolds stress tensor $\overline{u'_i u'_j}$ is unknown and has to be modelled
- Modelling should use the available quantities $(\bar{u}, \bar{v}, \bar{w}, \bar{p})$

Usefulness

- If the averaged results are useful for the engineers
- i.e. the fluctuation are not interesting “only” their effect on the mean flow
- If modelling is accurate enough

Lohász

Scales of
Turbulence

Transport
equation of k

Modelling

Eddy Viscosity

Two equations
models

Boundary
Conditions

Inlet Boundary
Conditions

In equations...

- Only the deviatoric part is modelled
- The trace (k) can be merged to the pressure (modified pressure), and does not need to be modelled
- Modified pressure is used in the pressure correction methods to satisfy continuity (see Poisson eq. for pressure)

$$\overline{u'_i u'_j} - \frac{2}{3} k \delta_{ij} = -2\nu_t \overline{S_{ij}} \quad (36)$$

Eddy Viscosity

Turbulence
and its
modelling

Máté Márton

Scales of
Turbulence

Transport
equation of k

Modelling
Eddy Viscosity

Two equations
models

Boundary
Conditions

Inlet Boundary
Conditions

Viscosity is a product of a length scale (l') and a velocity fluctuation scale (u')

- The length scale has to be proportional to the distance, what the fluid part moves by keeping its momentum
- The velocity fluctuation scale should be related to the velocity fluctuation caused by the motion of the fluid part

$$\nu_t \sim l' u' \quad (37)$$

Newer results supporting the concept

Coherent structure view of turbulence, proves that there are fluid parts (vortices) which keep their properties for a while, when moving

Two equations models

Turbulence
and its
modelling

Máté Márton
Lohász

Scales of
Turbulence

Transport
equation of k

Modelling

Eddy Viscosity

**Two equations
models**

Boundary
Conditions

Inlet Boundary
Conditions

- Length (l') and velocity fluctuation scales (u') are properties of the flow and not the fluid, they are changing spatially and temporally
- PDE's for describing evolutions are needed

Requirements for the scales

- Has to be well defined
- Equation for its evolution has to be developed
- Has to be numerically “nice”
- Should be measurable easily to make experimental validation possible

k-e modell

Turbulence
and its
modelling

Máté Márton
Lohász

Scales of
Turbulence

Transport
equation of k

Modelling

Eddy Viscosity

Two equations
models

Boundary
Conditions

Inlet Boundary
Conditions

Velocity fluctuation scale

- TKE is characteristic for velocity fluctuation
- It is isotropic (has no preferred direction)

$$u' \sim \sqrt{k} \quad (38)$$

Length scale

- Integral length scale is well defined (see correlations)
- No direct equation is easy to develop
- Length scale is computed through the dissipation

Recall: $\varepsilon = \frac{u_0^3}{l_0} \Rightarrow l' \sim \frac{k^{3/2}}{\varepsilon}$

Equation for the eddy viscosity

Turbulence
and its
modelling

Máté Márton
Lohász

Scales of
Turbulence

Transport
equation of k

Modelling

Eddy Viscosity

Two equations
models

Boundary
Conditions

Inlet Boundary
Conditions

$$\nu_t = C_\nu \frac{k^2}{\varepsilon} \quad (39)$$

C_ν is a constant to be determined by theory or experiments...

Our status...?

- We have two unknown (k, ε) instead of one (ν_t)

k model equation

Equation for k was developed, but there are unknown terms:

$$\partial_t k + \overline{u_j} \partial_j k = \underbrace{-a_{ij} \overline{S_{ij}}}_{\text{Production}} + \partial_j \underbrace{\left[\overline{u'_j \left(\frac{p'}{\rho} + k' \right)} - \nu \overline{u'_i S'_{ij}} \right]}_{\text{Transport}} - \underbrace{\varepsilon}_{\text{Dissipation}} \quad (40)$$

Production

Production is directly computable, by using the eddy viscosity hypothesis

$$\mathcal{P} = -a_{ij} \overline{S_{ij}} = 2\nu_t \overline{S_{ij}} \overline{S_{ij}} \quad (41)$$

Filtering

Filtered equations

Subgrid-scale

- Turbulence is mainly produced in the buffer region ($5 < y^+ < 30$)
- Turbulence is viscously diffused to the wall
- Turbulence is strongly dissipated at the wall
- Conclusion: $\varepsilon = \nu d_{y^2}^2 k \quad @ y = 0$

Filtered
equations

In this treatment the complete boundary layer is resolved numerically

When to do?

- Low Reynolds number flow, where resolution is feasible
- If boundary layer is not simple, can not be described by law of the wall

How to do?

- Use a turbulence model incorporating near wall viscous effects
- Use appropriate wall resolution ($y^+ < 1$)

Numerical treatment of the wall layer, actual BC's

Filtered
equations

In this treatment the first cell incorporates the law of the wall

When to do?

- High Reynolds number flow, where it is impossible to resolve the near wall region
- If boundary layer is simple, can be well described by law of the wall

How to do?

- Use a turbulence models containing law of the wall BC
- Use appropriate wall resolution ($30 < y^+ < 300$)

Numerical treatment of the wall layer, actual BC's

Concept of LES

Filtering

Filtered
equations

The mixture of the two methods is developed:

- to enable the engineer not to deal with the wall resolution
- usually the mixture of the two method is needed, depending on actual position in the domain

Resolution requirements

At **any kind** of treatment the boundary layer thickness (δ) has to resolved by ≈ 20 cells to ensure accuracy.

equations

Simulation

In the simulation the turbulence phenomena is actually resolved by a numerical technique, by solving the describing equations

Modelling

In the modelling of turbulence the effects of turbulence are modelled relying on theoretical and experimental knowledge. In the computation a reduced description of turbulence is carried out

equations

Sub-grid scale

The NS equations (describing completely the turbulence phenomena) are solved numerically

Difficulties

- The scales where the dissipation is effective are very small
 - The size of the smallest scales are Reynolds number dependent
- Simulation is only possible for academic situations (e.g.: HIT on $64 \cdot 10^9$ cells)

Filtered
equations

Compromise between RANS and DNS

- RANS: feasible but inaccurate
- DNS: accurate but infeasible

The large scales are important to simulate

- The large scales of the turbulent flow are boundary condition dependent, they need to be simulated
- The small scales of turbulence are more or less universal and can be modelled 'easily'
- The removal of the small scales from the simulation reduce the computational cost remarkably

DNS

Concept of LES

Filtering

Filtered
equations

- G_Δ is the filtering kernel with a typical size of Δ .
- G_Δ has a compact support (its definition set where the value is non-zero is closed) in its first variable
- To be the filtered value of a constant itself it has to be true:

$$\int_V G_\Delta(r_i; x_j) dr_i = 1 \quad (59)$$

- If $G_\Delta(r_i; x_j)$ is homogeneous in its second variable and isotropic in its first variable than $G_\Delta(|r_i|)$ is a function of only one variable

DNS

Concept of LES

Filtering

Filtered
equations

- Same as in RANS

$$\tau_{ij} - \frac{1}{3}\tau_{kk}\delta_{ij} = -2\nu_t \langle s_{ij} \rangle \quad (64)$$

- Relatively a better approach since the small scales are more universal
- Dissipative if $\nu_t > 0$.

Subgrid-scale

$$\nu_t = (C_s \Delta)^2 |\langle S \rangle| \quad (65)$$

$$|\langle S \rangle| \stackrel{\text{def}}{=} \sqrt{2s_{ij}s_{ij}} \quad (66)$$

- C_s Smagorinsky constant to be determined
 - using spectral theory of turbulence
 - using validations on real flow computations
- Δ to be prescribed
 - Determine the computational cost (if too small)
 - Determine the accuracy (if too big)
 - 80% of the energy is resolved is a compromise

Sub-grid scale

Let us assume that the cuted small scales are similar to the kept large scales!

A logical model:

$$\tau_{ij} \stackrel{\text{def}}{=} \langle\langle u_i \rangle \langle u_j \rangle\rangle - \langle\langle u_i \rangle\rangle \langle\langle u_j \rangle\rangle \quad (67)$$

Properties

- It is not dissipative enough
- It gives feasible shear stresses (from experience)
- Logical to combine with Smag. model!
